# 1 Summary

Based on the given feedback, we continued working on the project with the aim of preparing a comprehensive empirical study on the given dataset and defined problem. Our analysis includes performing: (1) raw data analysis to gain insight on the dataset from various statistical perspectives, (2) unsupervised learning to evaluate its performance on the defined problem and the given dataset, (3) supervised learning to evaluate its performance on the defined problem and the given dataset, and (4) analysis on the implementation of application programming interface (API) as the last step when we deploy the trained model for usage. The detailed explanations and results are given in the following sections. The detailed code, analysis, and explanations of our progress can be found in these github links: [link1](#), [link1](#), [link1](#).

# 2 Problem Statement

Diabetes Mellitus is among critical diseases and lots of people are suffering from it in recent years. According to the recent studies, age, obesity, lack of exercise, hereditary diabetes, living style, bad diet, high blood pressure, etc. can cause Diabetes Mellitus. People having diabetes have high risk of diseases such as heart disease, kidney disease, stroke, eye problem, and nerve damage. With the recent advancements in the field of machine learning (ML), several researchers have tried to apply ML models to perform Diabetes prediction in patients based on various factors. However, there is no rigorous and comprehensive study on the evaluation of different ML models to determine the best practices in this specific problem.

In this project, we aim at implementing and evaluating different classification methods (e.g., decision tree, random forest, support vector machine, and neural network) on the given dataset. We will use the Pima Indians onset of diabetes dataset. This is a standard machine learning dataset from the UCI Machine Learning repository. It describes patient medical record data for Pima Indians and whether they had an onset of diabetes within five years.

# 3 Detailed Data Analysis

Our dataset includes 768 data points, each of which having 8 features and 1 label. For Each row in the dataset (all numeric-valued), we have the following columns:

- Number of times pregnant
- Plasma glucose concentration a 2 hours in an oral glucose tolerance test
- Diastolic blood pressure (mm Hg)
- Triceps skin fold thickness (mm)
- 2-Hour serum insulin (mu U/ml)
- Body mass index (weight in kg/(height in m)<sup>2</sup>)

- Diabetes pedigree function
- Age (years)
- Class variable or label (0 or 1) - 1 represents the positive diabetes and 0 denotes the negative diabetes

First, we started by performing data analysis on the given dataset to gain insight on it from various points of view. The data type for each of the dataset columns is as:

- Pregnancies int64
- Glucose int64
- BloodPressure int64
- SkinThickness int64
- Insulin int64
- BMI float64
- DiabetesPedigreeFunction float64
- Age int64
- Outcome int64

Also, the below figure shows the statistical information (i.e., count, average, standard deviation, minimum, maximum, 25%, 50%, and 75%) on each of the dataset columns.

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
count	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000
mean	3.845052	120.894531	69.105469	20.536458	79.799479	31.992578	0.471876	33.240885	0.348958
std	3.369578	31.972618	19.355807	15.952218	115.244002	7.884160	0.331329	11.760232	0.476951
min	0.000000	0.000000	0.000000	0.000000	0.000000	0.000000	0.078000	21.000000	0.000000
25%	1.000000	99.000000	62.000000	0.000000	0.000000	27.300000	0.243750	24.000000	0.000000
50%	3.000000	117.000000	72.000000	23.000000	30.500000	32.000000	0.372500	29.000000	0.000000
75%	6.000000	140.250000	80.000000	32.000000	127.250000	36.600000	0.626250	41.000000	1.000000
max	17.000000	199.000000	122.000000	99.000000	846.000000	67.100000	2.420000	81.000000	1.000000

Figure 1: Statistical analysis on the dataset columns.

According to this figure, we can see that the average value for the output label column is 0.34 which implies that the dataset is imbalanced and the number of 0s is more than the number of 1s. We have verified this by plotting the count of each labels as shown in Figure 2. Another important observation was that some features like Glucose, Blood pressure , Insulin, BMI have zero values which represent missing data in the dataset.

Now, let's discuss the importance of the features and their overall affect on the labels of the dataset. A heatmap is a graphical representation of data that uses a system of color-coding to represent different values. Here, a heatmap graph can show the correlation between the features and the output label. Based on the results, one can easily determine which features are the most important ones in the dataset.

From the correaltion heatmap, we can see that there is a high correlation between

Figure 2: The number of positive and negative diabetes in the dataset.

Figure 3: Heatmap graph of the given dataset illustrating the correlation between various columns.

Outcome and Glucose,BMI,Age features. In a practical scenario like our case, we can select these features in our website to accept input from the user and predict the outcome. An alternative would be making these features mandatory inputs and make the others optional to a user to predict how likely he/she will be diagnosed with Diabetes. These results are consistent with the pair plots and violin plots that are given in the [notebook](#). In addition to this, the violin plot shows that the BloodPressure feature is almost useless as it's violin shape is pretty similar for the given lables in our dataset. To visuallly gain further insight on the features, we can plot their probaility distribution functions (pdfs). In the perfect scenario, all the features must be represented by normal distribution. However, as can be seen, we don't have such distribution here.

Figure 4: pdf distribution of different features in the dataset.

## 4 Unsupervised Learning

In the previous section, we performed statistical analysis on our dataset to gain some insight on the features, their distribution, their importance (effect) on the prediction classes. In the next step, we will try to find the boundary between the labels with unsupervised learning. This can be done by separating the dataset into two different parts (clusters) and then see how much of the ground truth labels are matching the separated labels using the unsupervised learning approach.

### 4.1 K-Means Clustering

One of the most famous unsupervised learning algorithms is K-means, which classifies the dataset into  $k$  different clusters. In our case, we already know that  $k = 2$ . Implementing the K-means cluster with  $k = 2$ , we obtained the following confusion matrix results. It is obvious that the K-means clustering algorithm return very poor results in terms of the accuracy, precision, and recall. To show this interpretation, we also plot the actual data points and the clustered ones. Figure 6 shows both the actual dataset and the clustered one. As can be seen in the 2D representation of the dataset, the clustered dataset has so many wrong classified data points that causes its performance drop. Based on this observation, it is obvious that unsupervised learning is not able to classify the given dataset with reasonable accuracy, and hence, we will try to use supervised learning techniques in the next sections.

## 5 Supervised Learning

We implemented multiple well-known supervised learning algorithms (i.e., artificial neural network, support vector machine, random forrest) on the given dataset. The accuracy of the trained models are 0.67, 0.759, and 0.818 which are associated with ANN, SVM, and Random Forrest models, respectively. Based on the obtained results, it seems that the Random Forrest reveals the best performance on this dataset. However, we noticed that the performance of the trained models are heavily depend on their hyperparameters and we cannot make a general conclusion about the superirity of a specific model. In fact, one can train an ANN model with the higher performance than that of the Random Forrest. Another important point is that the performance of the supervised learning algorithms is much better than that of the unsupervised learning method we used earlier. The reason behind this observation is that we use additional useful information (data point labels) in the training phase and this leads to better overall performance. The detailed code and results associated with the supervised learning algorithms can be found in [here](#) and [here](#).

Figure 5: Confusion matrix obtained from the K-means algorithm.

Figure 6: The clustered and actual representation of the dataset.

## 6 Application Programming Interface (API)

The API we are developing for this application is a Flask-RESTful API which has been developed in python. This API gets the features of a sample data point as input in a json data format for an http POST request and predicts the probability of the diabetes for the given input. The trained model gets serialized and saved as a pickle file and the API loads the pickle file and then makes a prediction based on the de-serialized model object. For the input, we considered the most important features (i.e., Glucose, BMI, Age) as mandatory and the others as optional. If the user does not provide the optional features, we replace them with the average values as they should not have significant effects on the model prediction according to our data analysis. As we know, we used classification methods to train our algorithm however, we are returning a float number as the output of the API. To achieve this in the neural network model, we do not discretize the final output of the neural network. Instead, we return the raw number which is between 0 and 1 as the probability of diabetes as it makes more sense in real life. The detailed code and explanation of the developed dataset can be found in [here](#). The API can be easily tested with a simple curl command in terminal as explained in the github readme file.
